FARM OPERATOR FAMILY LEVEL OF LIVING INDEXES FOR COUNTIES OF THE UNITED STATES, 1940 AND 1945

By Margaret Jarman Hagood, Social Scientist

During World War II, United States farmers generally became more prosperous. Because of record production and good prices, the average net income of farm operators from agriculture rose from \$768 in 1940 to \$2,251 in 1945. Even when rising living costs are taken into account, the gain for the five years was lll percent.

In order to determine the extent to which the increase in income resulted in improved living conditions, indexes of farm operator family level of living by counties have been constructed from 1940 and 1945 Censuses of Agriculture figures. The indexes show that in 1945 the level of living of farm operator families in the United States was one-fourth above 1940. The increases were general, the poorer counties gaining as well as the wealthier. In only about 1 percent of the counties did the level of living decline.

The indexes in this bulletin do not cover all of the goods, services and other satisfactions that make up the "level of living." However, the various items usually are closely associated. For instance, farm families with electricity are more likely to have other types of household facilities and conveniences, and in fact, better houses than those without electricity. An index based on a few of them will measure fairly accurately the over-all changes in the level of living.

The items on which the indexes of farm operator level of living are based include:

(1) The percentage of farms with electricity in the farm dwelling; (2) the percentage of farms with telephone in farm dwelling; (3) the percentage of farms with automobiles; and (4) the average value of products sold or traded in the preceding year per farm reporting (adjusted for changes in purchasing power). The indexes show only the average level of living for a county and do not throw any light on the differences among farm operator families within the county.

The average level of living for all counties in the United States in 1945 was selected as the starting point of 100, on which both the 1940 and 1945 indexes are based. This is not a perfect score nor does it represent a particular standard. It means only that a county is at about the average of all counties in 1945. In Table 1, for example, the average level of living of farm operators in the counties of the New England States in 1940 was 115 percent of the level of living of farm operators in all counties in the United States in 1945. An index number of "zero," on the other hand, represents about the lowest level of living possible in the United States. A county would receive zero only if there were no household electrical equipment, telephones, or automobiles on operators! farms and no farm products were produced for sale or exchange.

The Southern States had the lowest living level in both 1940 and 1945 but gained more on a percentage basis than the other regions. The East South Central Region gained 37 percent, while the two other southern regions increased their standing by more than 30 percent. However, the differences among the various regions were not extreme.

Table 1.-Average county index of farm operator family level of living for the United States, major regions and geographic divisions, 1940 and 1945 1/

1/ Computed from data from the 1940 and 1945 Censuses of Agriculture on four items related to level of living of farm operator families. Value for average county in the United States in 1945 equals 100 on 1940 and 1945 indexes; zero on the index scales represents zero values on all items for all farm operators in a county.

2/ Indexes for 1945 were computed for all counties that had some rural-farm population in 1940. Indexes for 1940 were computed for the same counties with the exception of 21 counties in the Lountain Division for which comparable data could not be obtained because of differences between the two censuses in obtaining information on Indians living on reservations in these counties.

Although the Southern divisions had the largest percentage gains, their index numbers did not increase as many points as those for other regions. The average for the county indexes in the Pacific Region was 29 points higher in 1945 than in 1940 but the average for the East South Central was only 13 points higher.

While the level of family living was higher for farmers in all parts of the country the differences among regions were about the same in 1945 as in 1940. (See accompanying map.) Counties in the highest fifth are concentrated in the heart of the Corn Belt, in the small industrialized States on the Northeast seaboard, and in California. Iowa has the largest single block of counties in the top group. All except a few of the counties in the lowest fifth are in the Southeast, most of them in the Eastern Cotton Belt and in the self-sufficing areas of the Southern Appalachians, especially in Eastern Kentucky.

In general, the counties in the next to lowest fifth are adjacent to those of the lowest fifth while those in the next to highest fifth are adjacent to the top group. The middle fifth are somewhat scattered but many of them are in the Plains States and the Southwest.

The county indexes apply only to farm operator families. Therefore, high index numbers for a county or area do not necessarily mean good living conditions for hired farm workers and their families. This is particularly true in California where a large proportion of the hired farm workers do not live on farms. Hired laborers also make up a large proportion of the agricultural working force in the areas of specialized agriculture in Connecticut, Massachusetts, Rhode Island, New Jersey and Delaware. In Iowa, where the level of living is high, the farm labor population is relatively small.

How to interpret the indexes. To use and interpret the county indexes correctly, several points should be kept in mind.

- (1) The indexes reflect only the average level of living among the farm operator families in a county and do not throw any light on the differences within a county.
- (2) The average level of living for all counties in the United States in 1945 is 100 for both the 1940 and 1945 indexes. An index number of 100 for a county does not mean that it is perfect, or that its farm operator families have attained a particular standard. It indicates only that a county is about at the average of all counties of the United States in 1945. An index number of 50 means that a county is approximately half way between the 1945 United States average and "zero." A "zero" index number represents about the lowest level of living possible in the United States. A county would receive zero only if all farmers in the county produced no farm products for sale or exchange, and did not have household electrical appliances, a telephone, or an automobile.
- (3) The index numbers for many counties were substantially higher in 1945 than in 1940 because the number of sub-marginal farm operators had been reduced. This gain was an addition to any increase in level of living among farm operator families which remained on their farms or among families which had replaced those who had left.
- (4) The data available do not cover many aspects of farm family living. As a result, the indexes must be regarded as approximations. They will not, in every case, correctly show how one county compares with all other counties on a given date. Nor will they measure exactly the changes in the 5-year period. Nevertheless, the various goods, services, and other satisfactions that make up the "level of living," as the term is generally used, are usually highly intercorrelated. For this reason an index based on only four items will measure changes in many of the other items in the level of living.

Table 2.-Farm operator family level of living indexes, 1945 and 1940. (United States county average for 1945 equals 100 on 1940 and 1945 index scales.)

			appropriate the same							The comment of the Control of the Co

Note: The index value shown for a State is the unweighted average of the index values for counties of that State.

I/ Indexes for 1940 were not computed for 11 counties in Arizona, 9 in New Mexico, and 1 in Colorado. Comparable data could not be obtained for these 21 counties because of differences between the two censuses in obtaining information on Indians living in reservations in these counties. The 1945 indexes shown for these counties are based on returns that do not include Indians on reservations.

APPENDIX ON LETHODS USED IN CONSTRUCTING THE INDEXES

The methods used in constructing the county indexes of farm operator family level of living were similar to those used in constructing rural-farm and rural-nonfarm county indexes of level of living published by the Bureau of Agricultural Economics in 1940. Description of these methods and discussion of the concept of level of living which the indexes attempted to measure may be found in the following publications:

"Rural Level of Living Indexes for Counties of the United States, 1940,"
Bureau of Agricultural Economics, Washington 25, D. C., October 1943,
43 pp.

"Development of a 1940 Rural-Farm Level of Living Index for Counties," and "Rural Level of Living Indexes," by Margaret Jarman Hagood, in Rural Sociology, 8: pp. 171-180, June 1943, and 8: pp. 292-293, September 1943.

"What Level of Living Indexes Measure," by Margaret Jarman Hagood and Louis J. Ducoff, in American Sociological Review, 9: pp. 78-84, February 1944.

A more complete account of the methods used in constructing the indexes in this report than is given in this appendix may be found in the following publication:

"Construction of County Indexes for Measuring Change in Level of Living of Farm Operator Families, 1940-45," by Margaret Jarman Hagood, in Rural Sociology, 12: June 1947.

Construction of index formula.— Construction of the formula for combining information on the items in the indexes involved the obtaining of weights through component analysis of the intercorrelations among the four items. This method of obtaining weights assumes that the items should be combined in such a way as to provide a composite measure of the highest factor they have in common. This is the factor which can best be measured by the given items and it is assumed to represent an approximation to "level of living."

To expedite the construction of the indexes, the preliminary work was limited to a national sample of 196 counties. With certain supplementary counties, this was used by the Bureau of the Census for early processing of the results from the 1945 Census of Agriculture to obtain national and regional estimates before complete tabulations were available. The stages in development of the index formula from the correlations for this sample of counties is shown in Table 3. The formula for 1945 is as follows:

$$1945 \text{ Index} = .538X_1 + .603X_2 + .617X_3 + .460X_4$$

with the subscripts of the items referring to the identification numbers used in Table 3.

Table 3.—Stages in development of index formula from intercorrelations of four items related to farm operator level of living, sample of 196 counties, 1945

1/ Identification of items:

1 = Percentage of farms with electricity in farm dwelling, 1945.

2 = Percentage of farms with telephone in farm dwelling, 1945.

3 = Percentage of farms with automobiles, 1945.

4 = Mean value of products sold or traded per farm reporting, 1944 (in hundreds of dollars).

One modification was required in the formula for use in computing comparable index values for 1940. To allow for the higher purchasing power of the farmers dollar in 1939 than in 1944, the average value of products sold or traded as reported for 1944 could have been increased by 37.1 percent before applying the 1945 index formula. For computing purposes it was simpler to multiply the weight for this item, X4, by 1.371. This results in the following formula for 1940 data:

1940 Index =
$$.538X_1 + .603X_2 + .617X_3 + .631X_4$$
,

with the subscripts of the items referring to the identification numbers used in Table 3.

Problem of treatment of Indians in 21 counties.— It may be noted that 1940 index values are not shown in table 2 for 11 counties in Arizona, 9 counties in New Mexico, and 1 county in Utah. This is due to the fact that in these counties the 1945 Census of Agriculture did not obtain data on electricity, telephones, etc. for Indian families living on reservations, and hence the 1945 indexes for these counties reflect primarily non-Indian farm operators. The 1940 Census data related to both Indian and non-Indian farm operators. Indexes could be shown for either 1940 or 1945 but not for the two dates on a comparable basis. Hence, the 1940 indexes were omitted. The effect of the omission on the 1940 averages for Arizona and New Mexico was so great that they are not shown. However, the effect on the average for Utah was so slight that it is included. The 1940 averages for the Mountain division, the West, and the United States also were only slightly affected and are shown with the 21 counties excluded. (For example, the United States average for 1940 rounds to 80, whether these 21 counties are excluded or included.)

Counties with marked changes in index values between 1940 and 1945.— All counties with index values that increased by more than 100 percent in the 5 years werd subjected to special study. There were 37 such counties, all in the South. They can best be described by classifying them into three groups. The first group includes 9 counties which had increases in the number of farms (over 100 percent in two cases) between 1940 and 1945. All except one had 1940 index values of less than 30, so that the large percentage gains do not represent a large absolute gain in index points. In most cases, these counties were close to centers of war industry or military establishment. This accounted for an increase in very small farms for residential purposes, with the operator's family having a relatively high level of living due to income from nonfarm employment. In one county, the increase in average level of living scems to have been caused by a trebling of land in farms through reclamation.

Counties with marked decreases in number of farms (15 percent or more reduction) made up the second group of 15. The major explanation for their marked percentage rise in level of living index was the actual elimination of many of the low income farming operations which had led to low index values for 1940. In most of these counties, there were striking increases in the average size of farm, average value of products, etc.

The third group of 13 counties had small or moderate decreases in number of farms during the period (decreases of less than 15 percent). Except for 3 Texas counties in this group, the 1940 index values had been very low in 1940 — between 8 and 17 for 7 of the counties. Thus small absolute gains showed up as large percentage increases. In the cases of the Texas counties (2 wheat and one range), the number of farms was very small, but the increases in the indexes appear to reflect bona fide rises in prosperity.
